## List of Appendices

Appendix A - Tree Inventory Drawings TI-1 to TI-11 and Tree Inventory Table

## 1. Introduction

CIMA+ has been retained by the City of Windsor (the City) to review the trees potentially affected by road work proposed along University Avenue and Victoria Avenue in downtown Windsor. The City is looking to transform a stretch of University Avenue approximately 3.75 km long and a crossing segment of Victoria Avenue 225 m long into an inviting, multimodal transportation corridor. This report will help determine the project's potential impacts on trees in the public realm as well as on trees on private property that may be affected by the work. This report will also provide general recommendations to avoid and/or mitigate tree loss and injury.

## 2. Limitations

The assessment presented in this report has been made using accepted standard arboriculture techniques as outlined in the Council of Tree and Landscape Appraisers Guide for Plant Appraisal, 9th Edition (2000). These techniques include visual examination of above ground parts of each tree or trees in each group. The trees observed were not climbed, cored, or dissected, and excavation for detailed root crown inspection was not performed. Since some symptoms may only be present seasonally, the extent of observations that can be made may be limited by the time of year in which the inspection took place.

Since trees are living organisms, their health and vigour continually change over time due to seasonal variations, changes in site conditions, and other factors. For this reason, the assessment presented in this report is valid at the time of inspection, and no guarantee is made about the continued health of trees that are deemed to be in good condition. It is recommended that the trees be re-assessed periodically to identify changes in condition. While every standing tree has the potential for failure and therefore poses some risk, a tree assessment is a good indication of present health and potential problems that could arise in the future.

CIMA+ has prepared this report for the sole use of the client. Any use of this report by a third party, as any decision based on this report, is the singular responsibility of the third party.
CIMA+ will not be held responsible for eventual damages towards a third party resulting from decisions taken, or based, on this report.

## 3. Methodology

An ISA Certified Arborist from CIMA+ visited the site on July 5 and 6, 2018.
Trees and vegetation groups were located within the public right-of-way and along adjacent private property where effects of road work could affect trees. This would typically occur wherever a private tree's canopy may overhang into the right-of-way. Vegetation groups were also noted instead of individual trees or shrubs in certain cases: where a group of very similar trees or shrubs were located together or where significant planting beds may exist beneath tree and be affected by proposed work.

Trees and vegetation groups were uniquely numbered, identified, measured, and assessed for condition. The assessment methodology is outlined in Section 3 below. The tree inventory tables containing this information are included in Appendix A along with drawings $\mathrm{TI}-1$ through TI-11 that show the the locations of the numbered trees and groups surveyed.

### 3.1 Tree Size

Size refers to trunk diameter (caliper or DBH) measured in centimetres at 1.4 m above the ground. Where trees had more than one trunk from the base, the size of each trunk was recorded. Where trees forked to codominant trunks, each trunk was measured or the diameter was measured under the flare and the approximate height of the measurement was noted.

### 3.2 Observations

Several structural defects and health problems are included in the Comments section of the tree inventory and assessment table. Following is an explanation of the short forms used in the table:

GR Girdling roots
COD Codominant trunks or codominant leaders
NA Narrow branch angles
INCL Included bark
CRB Crossing branches
MBR Multiple branches from the same point of attachment
DPR Decay at pruning wounds
SMD Small dead branches
ADV Adventitious shoots
These observations, along with other terms related to describing tree conditions, are defined below.

Structural defects are often insignificant when a tree is small, but can pose problems when the tree grows larger and the weight of branches put added stress on defects that can cause weakness. Larger trees also have the potential to cause more damage should they fail. The following is an explanation of some of the observations included in the inventory and assessment table, and how they can affect trees over time.

- Adventitious shoots are vigorous growth of shoots from pruning cuts, inner branches, or along the trunk that usually occur in response to stress.
- Codominant leaders (2 trunks or branches of approximately equal size) often have narrow branch angles, and are associated with weak branch attachment. Strong branch attachments occur between 2 limbs of unequal size with enough space for branch enlargement and formation of a branch bark ridge.
- Crossing branches are often associated with narrow branch angles. Branches that cross over each other often rub, causing damage and therefore weakness to one or both branches, and crossing branches can eventually girdle each other.
- Decay at pruning wounds can occur when pruning (or other bark-penetrating abrasions) expose a tree's heartwood, which can then be affected by a rot-causing fungi. The decay can lead to cavities and internal decay, and potentially affect the structural integrity of the tree.
- Exposed surface roots can be a result of erosion and soil compaction combined with increasing root diameter. It is important to protect exposed roots from pedestrian and vehicular traffic, and lawn mowers. Damage to roots can cause stress and can result in canopy dieback.
- Frass is the excrement of insect larvae, with an appearance similar to sawdust or small wood chips that can be seen at the base of a tree where wood boring insects are feeding. Frass can be an indicator of internal decay.
- Fruiting bodies are often recognized as mushrooms or conks on trees. Presence of fruiting bodies is a positive indicator of wood decay, but depending on the species of the fruiting body, the decay can be of little significance or an indicator of imminent failure. It is important to observe decay fungi during the season in which it is growing to accurately identify the species and consider the potential associated indications of the extent of decay.
- Girdling roots are roots that cross over each other or around the trunk of the tree. As these roots grow larger, they can restrict the uptake of nutrients and water, and inhibit structural anchorage.
- Included bark is bark that has become embedded in a crotch where limbs join, and causes weakened branch attachments. As the trunk and branch increase in diameter, the bark of each stem in the tight crotch begin to push apart, increasing the likelihood of failure.
- A tree with a lean can be more susceptible to windthrow and soil failure. Self-correcting lean refers to a natural correction of the lean by development of new growth that counteracts the lean of the trunk to provide a more balanced form.
- Lion tailing refers to branches that have a tuft of foliage at the end like a lion's tail, due to pruning of the inner branches. Branches that have been pruned in this way are end-heavy and more likely to fail.
- Live crown ratio is the ratio of the live crown to the overall height of the tree. A low live crown ratio can develop when trees are growing close together in stands, or can be created by pruning or dieback. Low live crown ratio is associated with increased likelihood of failure, depending on the cause and site factors.
- When a tree has multiple branches from the same point of attachment, the branches usually have characteristics of weakly attached branches.
- Narrow branch angles, especially where there is included bark, can be a problem as trees grow larger because the inner wood is poorly attached.
- Ribs and seams are often associated with included bark, but can also indicate internal defects or decay that cause irregular growth.
- The root flare refers to the base of the trunk where it widens as it transitions to the root system.
- Sapsucker holes refers to holes in the trunk or branches made by birds in search of insects. This damage is a sign of insects in the tree, and can make trees more susceptible to other infection.
- Small dead branches are an indicator of crown dieback and can be an early sign of stress.
- Split-gill fungus (Schizophyllum commune) is an extremely common fungus that often affects trees that with recently killed bark. It can spread to healthy tissues after establishment.
- Staghorn effect refers to dead branches protruding through the crown of a tree, and often indicates a state of significant decline.
- Suppressed trees are growing under the canopies of neighbouring trees, which can diminish vigour and affect structural form.
- Woundwood is the thickened tissue growing around the edges of a wound. The rate of its development can be a sign of the tree's vigour.

The detailed observations made concerning tree species, size, and condition are included in the tree inventory and assessment table in Appendix A.

### 3.3 Tree Condition

Each tree was given a subjective rating for trunk integrity, canopy structure, and crown vigour, and an overall health condition rating of Excellent, Good, Fair, Poor, or Dead. The following is a summary of how the ratings are determined:

- EXCELLENT (E): no apparent health problems; good structural form
- GOOD (G): minor problems with health and/or structural form
- FAIR(F): more serious problems with health and/or structural form
- POOR (P): major problems with health and structural form
- DEAD (D): dead

### 3.4 Tree Protection and Compensation

The spread area (dripline, measured here as a diameter) of each tree canopy is included to help determine possible injury and branch pruning that may be required.

Tree impacts (protection, injury, or removal) will be evaluated and considered during the design process.

## 4. Summary

A total of 267 trees and tree groups were surveyed along University and Victoria Avenues. This total is comprised of 226 individual trees and 41 individual shrubs and vegetation groups.

### 4.1 Structure of the Urban Forest

The size class of trees is an important metric for managing urban tree populations, as they indicate the relative age of trees as well as tree maintenance requirements. The ideal distribution is skewed left, with the greatest number of trees in the smallest DBH class decreasing to the least number of trees in the largest DBH class. This adds longevity and resiliency to the flow of functional benefits provided by the urban tree population, including aesthetic and ecological benefits.

The graph below illustrates that the tree size distribution for University Avenue is generally skewed to the left, with a significant drop in tree counts beyond the 40 cm DBH threshold. Trees less than 40 cm DBH make up almost $75 \%$ of all trees surveyed. Generally, the graph below shows a healthy tree size distribution. The relative disparity in numbers between trees less than 40 cm DBH and those above 40 cm DBH indicates that the future forest is promising. It is possible that the difference in size class at the 40 cm DBH threshold may indicate that municipal urban forestry management practices may favour removing larger trees as their hazard potential and their maintenance cost increases over time.

Figure 1. Tree size distribution in the study area.

### 4.2 Biodiversity of the Urban Forest

There were 35 tree species identified in total, with 28 genera and 18 families represented. A guideline for diversity in urban forestry is the 10-20-30 rule (as originally proposed by Frank Santamour in 1990 in his paper Trees for urban planting: Diversity, uniformity, and common sense). This rule maintains that an urban tree population should not have over $10 \%$ of any single species, over $20 \%$ of any single genus, or over $30 \%$ of any single family represented. This guideline promotes resiliency to specialized pests and disease, and offers protection against environmental stressors, as well as ecological benefits.

Following this rule, the graphs below indicate that honey locust and Norway maple both exceed the $10 \%$ species rule (at $16 \%$ and $14 \%$ respectively); that maples generally are slightly overrepresented as a genus (at 23\%); and that family diversity among trees along University Avenue is well under the $30 \%$ mark, with the pine, legume, and rose families tied for the highest share at $11 \%$ each.

Compared to many urban streets, the species diversity of the trees inventoried along University Avenue is very good.

Figure 2. Tree species distribution in the study area ( $\mathrm{n}=35$ species).

Figure 3. Tree genera distribution in the study area ( $\mathrm{n}=\mathbf{2 8}$ genera).

Figure 4. Tree family distribution in the study area ( $\mathrm{n}=16$ families).

### 4.3 Information About Individual Trees, Shrubs, and Vegetation Groups

Please see Appendices $A$ and $B$ for further descriptions and locations of each tree and vegetation group.

## 5. Protected Species

The Migratory Birds Convention Act, 1994 protects the nests of migratory birds. This effectively means that trees to be removed from the site should be removed outside of the migratory birdnesting window, the timing of which differs regionally across Canada as determined by Environment Canada. Following Environment Canada's guidelines, the window at this site is from April 1 to August 31. Trees may be removed during this restricted period only when trees are inspected for nests of protected bird species by a qualified avian biologist immediately prior to removal.

A Kentucky coffeetree (Gymnocladus dioicus) was found as a specimen tree on property of the University of Windsor adjacent to the right-of-way (Tree 145). Kentucky coffeetree is a protected species under the Ontario Endangered Species Act, 2007, however, as a specimen tree in the landscape, it is assumed to be commercially cultivated and exempt from protection under Section 12 of O. Reg. 242/08. No other species at risk were found.

## 6. Recommendations

The most typical construction damage to trees is root damage from compaction and severance. While the dripline of a tree's canopy is typically thought to be associated with the root area, the root zones can actually extend significantly beyond the dripline of the tree, sometimes up to 2 or 3 times the height of the tree. Some of the trees inventoried are growing close to the edge of the potential construction area and will be at risk of contact with, and damage from, heavy equipment. It is recommended that tree protection fencing be installed around such trees once the limit of disturbance is known.

Generally, to protect trees, grade changes and construction activities that could cause soil compaction should be kept away from trees as much as possible. If soil compaction from heavy equipment is anticipated, tree protection fence can exclude equipment from areas within a tree's dripline, or, if this is not possible, plywood or iron plates can be laid on top of mulch over the rooting area to mitigate soil compaction. If roots will be damaged by excavation equipment, it is better to cut roots cleanly with sharp pruning tools rather than allow them to be torn by large equipment. Clean cuts will help to minimize decay and entry points for disease. If branches are likely to hang in the way of passing equipment, the branches should be pruned by a qualified arborist to avoid tearing and undue injury to the tree.

Equipment and materials should not be stored near trees, and equipment should not be left idling where exhaust could burn foliage.

Future delineation of construction limits throughout the study area in combination with this inventory will determine the potential tree injury, removal, and protection measures required by the proposed work.

## 7. Certification and Closure

We certify that all the statements of fact in this assessment are true, complete, and correct to the best of our knowledge and belief, and that they are made in good faith.
